NAPEN-D

Honorable Brendan T. Byrne Governor of New Jersey Trenton, New Jersey 08621

1 5 MAY 1979

Dear Governor Byrne:

Inclosed is the Phase I Inspection Report for West Branch Reservoir Dam in Somerset County, New Jersey which has been prepared under authorization of the Dam Inspection Act, Public Law 92-367. A brief assessment of the dam's condition is given in the front of the report.

Based on visual inspection, available records, calculations and past operational performance, West Branch Reservoir Dam, a high hazard potential structure, is judged to be in good overall condition. The dam's spillway is considered inadequate since 26 percent of the Spillway Design Flood - SDF - would overtop the dam. (The SDF, in this instance, is the Probable Maximum Flood). The decision to consider the spillway "inadequate" instead of "seriously inadequate" is based on the fact that failure resulting from overtopping would not significantly increase the hazard to loss of life downstream from that which would exist just prior to overtopping failure. To insure adequacy of the structure, the following actions, as a minimum, are recommended:

- a. The spillway's adequacy should be determined by a qualified professional consultant engaged by the owner using more sophisticated methods, procedures, and studies within six months from the date of approval of this report. Operation of the reservoir at lower levels should be considered. Any remedial measures necessary to insure the adequacy of the spillway and to prevent overtopping should be initiated within calendar year 1980. In the interim, a detailed emergency operation plan and warning system, should be promptly developed. Also, during periods of unusually heavy precipitation, around-the-clock surveillance should be provided.
  - b. Within six months from the date of approval of this report,

NAPEN-D Honorable Brendan T. Byrne

engineering studies and analyses should be performed to determine the dam's embankment and foundation condition and structural stability. This should include test borings to determine material properties relative to stability and seepage and installation of piezometers to facilitate seepage studies. Any remedial measures found necessary should be initiated within calendar year 1980. The dam should be surveyed and survey markers should be installed for future monitoring.

- c. The following remedial actions should be completed within six months from the date of approval of this report:
- (1) Repair the cracked and eroded areas of the spillway channel training wall.
- (2) Check the emergency outlet valves to see that they are functioning properly. Regularly operate the outlet in the future to check its performance.
- (3) Remove all shrubs and trees from the embankment and clean floating debris from the spillway area.
- (4) Inspect the dam annually, using the criteria set forth in the Corps of Engineers Guidelines.
  - (5) Keep records of all maintenance work.

A copy of the report is being furnished to Mr. Dirk C. Hofman, New Jersey Department of Environmental Protection, the designated State Office contact for this program. Within five days of the date of this letter, a copy will also be sent to Congresswoman Millicent Fenwick of the Fifth District. Under the provision of the Freedom of Information Act, the inspection report will be subject to release by this office, upon request, five days after the date of this letter.

NAPEN-D Honorable Brendan T. Byrne

Additional copies of this report may be obtained from the National Technical Information Services (NTIS), Springfield, Virginia 22161 at a reasonable cost. Please allow four to six weeks from the date of this letter for NTIS to have copies of the report available.

An important aspect of the Dam Safety Program will be the implementation of the recommendations made as a result of the inspection. We accordingly request that we be advised of proposed actions taken by the State to implement our recommendations.

Sincerely,

1 Incl As stated JAMES G. TON

Colonel, Corps of Engineers

District Engineer

#### WEST BRANCH RESERVOIR DAM (NJ00372)

#### CORPS OF ENGINEERS ASSESSMENT OF GENERAL CONDITIONS

This dam was inspected on 5 and 21 December 1978 by Jenny-Leedshill Engineers under contract to the State of New Jersey. The State, under agreement with the U. S. Army Engineer District, Philadelphia, had this inspection performed in accordance with the National Dam Inspection Act, Public Law 92-367.

West Branch Reservoir Dam, a high hazard potential structure, is judged to be in good overall condition. The dam's spillway is considered inadequate since 26 percent of the Spillway Design Flood - SDF - would overtop the dam. (The SDF, in this instance, is the Probable Maximum Flood). The decision to consider the spillway "inadequate" instead of "seriously inadequate" is based on the fact that failure resulting from overtopping would not significantly increase the hazard to loss of life downstream from that which would exist just prior to overtopping failure. To insure adequacy of the structure, the following actions, as a minimum, are recommended:

- a. The spillway's adequacy should be determined by a qualified professional consultant engaged by the owner using more sophisticated methods, procedures, and studies within six months from the date of approval of this report. Operation of the reservoir at lower levels should be considered. Any remedial measures necessary to insure the adequacy of the spillway and to prevent overtopping should be initiated within calendar year 1980. In the interim, a detailed emergency operation plan and warning system, should be promptly developed. Also, during periods of unusually heavy precipitation, around-the-clock surveillance should be provided.
- b. Within six months from the date of approval of this report, engineering studies and analyses should be performed to determine the dam's embankment and foundation condition and structural stability. This should include test borings to determine material properties relative to stability and seepage and installation of piezometers to facilitate seepage studies. Any remedial measures found necessary should be initiated within calendar year 1980. The dam should be surveyed and survey markers should be installed for future monitoring.
- c. The following remedial actions should be completed within six months from the date of approval of this report:
- (1) Repair the cracked and eroded areas of the spillway channel training wall.

- (2) Check the emergency outlet valves to see that they are functioning properly. Regularly operate the outlet in the future to check its performance.
- (3) Remove all shrubs and trees from the embankment and clean floating debris from the spillway area.
- (4) Inspect the dam annually, using the criteria set forth in the Corps of Engineers Guidelines.
  - (5) Keep records of all maintenance work.

APPROVED'

Colonel, Corps of Engineers

District Engineer

DATE: 11 May 1979

## PHASE I INSPECTION REPORT NATIONAL DAM SAFETY PROGRAM

Name of Dam: West Branch Reservoir

Federal I.D. No. NJ 00372

State Located: New Jersey
County Located: Somerset

Stream: West Branch Middle Brook
Dates of Inspection: December 5 and 21, 1978

#### Brief Assessment of General Condition of Dam

Structurally the dam appears to be in good overall condition, without any major discontinuities or evidence of distress. Certain repairs are needed, however, to assure the long-term integrity of the project.

The spillway of the dam is inadequate and can pass only about 25 percent of the Probable Maximum Flood. The dam has been overtopped once, causing considerable damage to the downstream embankment.

Information is generally lacking on the as-built physical properties and configuration of the dam. It is recommended that in the near future a program of soil borings and tests be initiated so that seepage and stability analyses can be performed. A survey of the dam and installation of survey markers on the dam for future monitoring are also recommended in the near future.

Because the dam and reservoir are no longer used for water supply, it is recommended that alternative methods of operating the reservoir at lower levels be investigated as soon as possible. A downstream warning system should also be implemented soon. Other recommendations for operation and maintenance should be implemented in the near future. These include repair of the spillway training wall, operation of the outlet valves, installation and monitoring of instrumentation devices, removal of vegetation and debris, maintenance of repair records, and annual inspection of the dam along with timely repairs.

More detailed and sophisticated hydraulic and hydrologic studies to more accurately determine the spillway capacity should be undertaken by the owner within six months. Remedial action, as a result of these studies, should be initiated within one year. In the interim a warning and evacuation plan should be implemented to provide adequate warning to downstream residents. Also, surveillance of the dam should be provided during periods of heavy precipitation.

Frank L. Panuzio, P.E.

#### PREFACE

This report is prepared under guidance contained in the Recommended Guidelines for Safety Inspection of Dams, for Phase I Investigations. Copies of these guidelines may be obtained from the Office of Chief of Engineers, Washington, D. C. 20314. The purpose of a Phase I Investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon available data and visual inspections. Detailed investigation, and analyses involving topographic mapping, subsurface investigations, testing, and detailed computational evaluations are beyond the scope of a Phase I investigation; however, the investigation is intended to identify any need for such studies.

In reviewing this report, it should be realized that the reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team. It is important to note that the condition of a dam depends on numerous and constantly changing internal and external conditions, and is evolutionary in nature. It would be incorrect to assume that the present condition of the dam will continue to represent the condition of the dam at some point in the future. Only through continued care and inspection can there be any chance that unsafe conditions be detected.

Phase I inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established Guidelines, the Spillway Test flood is based on the estimated "Probable Maximum Flood" for the region (greatest reasonably possible storm runoff), or fractions thereof. The test flood provides a measure of relative spillway capacity and serves as an aide in determining the need for more detailed hydrologic and hydraulic studies, considering the size of the dam, its general condition and the downstream damage potential.

PHASE I INSPECTION REPORT NATIONAL DAM SAFETY PROGRAM WEST BRANCH RESERVOIR DAM Federal I.D. No. NJ 00372 New Jersey I.D. No. 118

SECTION 1: PROJECT INFORMATION

#### 1.1 General

#### a. Authority

The National Dam Inspection Act, Public Law 92-367, 1972, provides for the National Inventory and Inspection Program by the U. S. Army Corps of Engineers. This report has been prepared in accordance with this authority, through contract between the State of New Jersey and Jenny-Leedshill Engineers. The State of New Jersey has also entered into an agreement with the U. S. Army Engineer District, Philadelphia, to have this work performed.

### b. Purpose of Inspection

The purpose of this inspection was to evaluate the general structural integrity and hydraulic adequacy of the dam, and to determine if the dam constitutes a hazard to human life or property.

## 1.2 Description of Project

### Description of Dam and Appurtenances

West Branch Reservoir Dam (variously called Bound Brook Reservoir Dam and Washington Valley Reservoir Dam) is an earthfill structure with a concrete core wall

which impounds a reservoir of 805 acre feet maximum capacity on West Branch Middle Brook. The dam is 330 feet long, 39 feet high and has an upstream slope of 3H:1V and a downstream slope of 2H:1V. Both sides of the embankment are faced with riprap. The spill-way is a concrete ogee structure at the left abutment and there is a downstream channel cut into natural bedrock. A 24-inch diameter emergency outlet is operated from a control tower in the reservoir. The water supply outlet has been abandoned.

#### b. Location

The dam is located in north central New Jersey, near Martinsville, in Somerset County. The location of the dam is shown on Plate 1.

#### c. Size Classification

The size classification of the dam, based on its 39-foot height and 805 acre-feet maximum storage capacity, is <u>small</u>. The criteria for size classification of dams are set forth in the Corps' Guidelines. A small size dam is defined as one in which the reservoir capacity is equal to or greater than 50 acre-feet and less than 1,000 acre-feet, and/or the maximum height of the dam is equal to or greater than 25 feet and less than 40 feet.

#### d. Hazard Classification

A highway bridge is 500 feet downstream of the dam, and the stream parallels Chimney Rock Road for about a mile through a narrow, steep sided valley. Within the valley are a large rock quarry plant and a filtration plant. Further downstream is the Borough of Bound Brook (population 10,500) where failure of the dam could result in extensive property damage and the loss of more than a few lives in the western portion of the borough where it appears that several

dozen houses and a public institution are in the flood plain. For this reason West Branch Reservoir Dam merits a high hazard classification.

e. Ownership

The dam is owned by Elizabethtown Water Company, Box 111, 1341 North Avenue, Plainfield, New Jersey

#### f. Purpose of Dam

07062.

The dam presently has no purpose. It was formerly used for municipal water supply.

#### g. Design and Construction History

The dam was constructed during the period October, 1928 to July, 1930. Clyde Potts of New York was the engineer for the Bound Brook Water Company, the builder of the dam. The dam was overtopped by floodwaters in the storm of August 1971, resulting in considerable erosion of the downstream embankment. The embankment was restored to the original design under the direction of John V. Dinan Company, Inc. Ownership of the dam apparently passed to the present owners in 1971 or 1972.

#### h. Normal Operating Procedures

There is little regulation of the reservoir, but the owner reports that the reservoir is lowered in anticipation of large storms. No other releases are made. The dam is periodically checked by the owner's supervisory personnel.

#### 1.3 Pertinent Data

- a. Drainage Area 6.3 square miles
- b. Discharge at Damsite
  - . Ungated spillway capacity at top of dam 5360 cfs.
- c. Elevation (ft. above MSL)

•	Top dam	194.5
	Spillway crest	187
	Top core wall	193

. Streambed at centerline of dam 155

. Upstream invert emergency outlet 161

d. Reservoir Length (feet)

. Maximum Pool 4400 . Spillway crest 3700

e. Storage (acre-feet)

. Spillway crest 465 . Top of dam 805

f. Reservoir Surface (acres)

. Top dam 46
. Spillway crest 33

g. Dam

. Type Earthfill with concrete core wall

Length 330 ft. (approx.)
Height 39 ft.
Top Width 15 ft.
Side Slopes - upstream 3H:1V - downstream 2H:1V

. Zoning Selected material puddled on upstream side of core wall

. Impervious Core Concrete core wall

## h. Spillway

. Type Concrete ogee

Length of weir 72.5 ft.

. Crest elevation 187 ft.

. U/S Channel Reservoir

. D/S Channel Excavated rock channel with

concrete training wall on

right side

## i. Regulating Outlets

- 24-inch diameter C.I. pipe and gate valves (emergency outlet)
- . Abandoned 20-inch diameter water supply outlet with sluice gate inlets in control tower

#### SECTION 2: ENGINEERING DATA

#### 2.1 Design

#### a. Geological Conditions

West Branch Reservoir Dam is situated near the head of a narrow gorge cut through the First Watchung Mountain near Bound Brook, New Jersey in the central portion of the Piedmont Lowlands Physiographic Province. The regional geology of this province is discussed in Appendix C to this report.

The dam is located totally on dark, hard, competent columar "Newark" basalt. The same rock has been used for the dumped rock facing on the dam. A 2-foot wide fault was reported during excavation of the right side of the dam. The spillway has been blasted out of the bedrock on the left abutment and a concrete channel wall constructed on the rock. The bare rock is exposed in the channel floor and left wall. It is highly jointed but appears to be competent.

Overburden in the immediate area of the dam site is shallow (less than 10 feet thick) and composed primarily of recent sandy alluvium in the streambed and what appears to be an old, weathered, bouldery till on the adjacent side slopes. This site is well south of the Wisconsin age glacial terminal moraine but it was covered by pre-Wisconsin glaciation.

The dam is located in Seismic Zone 1. This classification indicates that the dam would be subject to shaking from distant earthquakes.

#### b. Design Data

Correspondence indicates that the dam was originally

designed to carry a roadway over the crest, and early plans show two spillways, one at each abutment. The design was changed sometime prior to or during construction to exclude the roadway, to raise the dam 3 feet and to construct only one spillway at the left abutment.

Specifications and most plans that are available pertain to earlier designs. Based on available data, the dam is thought to be approximately as represented in plan on Plate 2. The site topography and an earlier design of the dam are shown on Plate 3.

Typical sections of the dam are illustrated on Plate 4, and with the exceptions of the two spillways and the crest elevations, they are believed to represent the asbuilt design. Specifications indicate that the embankment material was to be compacted in horizontal layers of 6 inches or less thickness. Two classes of concrete were specified. The core wall was specified to be Class B concrete, consisting of 1 part Portland cement, 2-1/2 parts sand and 5 parts broken stone and gravel.

## 2.2 Construction

Inspections were made periodically during construction by the State, and reports on these inspections are available. They indicate that the foundation trench for the core wall was excavated an average of 1 to 3 feet depth to reach sound rock. No grouting was done, as the foundation rock was considered to be good quality with only hairline cracks.

Material for the embankment was excavated from the reservoir area and spread and compacted with a 5-ton bulldozer. Apparently no roller was used. The material was described as "a clayey earth carrying about 30 percent of broken and weathered trap fragments averaging

two inches in size". Selected material was puddled adjacent to the core wall on the upstream side.

The core wall was poured in a continuous operation over a period of 6 days. A vertical crack developed in the wall from the top to within 6 feet of ground level. The crack was treated with bitumen and muslin.

While excavating for the west spillway, a 2-3 feet wide fault was encountered in the bedrock. It was cleaned out and filled to a depth of 12 feet with concrete. Because of the presence of the fault, the plans were changed to eliminate the west spillway, to extend the core wall into this area, and to construct a larger spillway at the east end of the dam. The downstream spillway channel was to have been lined with concrete, but the quality of the bedrock was sufficiently good that lining was not required.

The spillway is shown in plan on Plate 5. The stone paving indicated on the downstream side of the weir was eliminated during construction because of the good quality bedrock. The spillway was constructed with a groove in the crest designed to accommodate flashboards. The flashboards were attached to the crest by steel ties and were designed to break away under high water level conditions. A request by the engineer to raise the spillway crest a foot higher than shown on the plans was denied by the State.

The dam was accepted by the State on June 2, 1930.

## 2.3 Operation

The reservoir is no longer used for water supply and is essentially unregulated. Periodic inspections are made by the owner's personnel.

#### 2.4 Evaluation

### a. Availability

Design drawings are available for an earlier design of the dam. Inspection reports made during construction are available, and there is correspondence in the State files regarding certain design and construction considerations. Most of the available data are listed in Appendix A.

#### b. Adequacy

Available data are insufficient to adequately evaluate the structural stability of the dam. Calculations relating to the structural design of the dam or the stability of the as-built structure are not available. Little is known of construction methods and nothing is known of materials testing or as-built material properties. There are no drawings representing the present geometry of the dam.

#### c. Validity

The available drawings of the embankment (Plates 3 and 4) represent an earlier design in which two spillways were proposed. Crest elevations on these drawings are incorrect. Drawings of the spillway (Plate 5) are substantially correct with regard to the geometry of the structure.

#### SECTION 3: VISUAL INSPECTION

#### 3.1 Findings

#### a. General

The visual inspection of the dam was made on December 5, 1978, and a subsequent inspection was made on December 21, 1978. At the time of the first inspection the reservoir level was 1.7 feet below the spillway crest. No water discharges were being made.

The visual inspection did not reveal any critical signs of distress in the dam. The remedial work to repair damage to the embankment following the 1971 storm appears to have been done in a satisfactory manner. The spillway channel training wall is cracked in places and eroded at the base, and there are certain maintenance matters that need to be attended to.

Detailed inspection was made of the dam, appurtenant structures, reservoir area, and the downstream channel. Descriptions of the findings of these inspections are summarized in the paragraphs which follow. The checklist of visual inspection items is included in Appendix A. Geologic and foundation conditions observed at the time of inspection are noted in greater detail in Section 2.1-a.

#### b. Dam

The dam was inspected for signs of settlement, seepage, erosion, cracking and any other evidence of undesirable behavior which might affect the stability of the structure.

The embankment appears to be in reasonably good

condition. It is completely covered with dumped rock riprap, and, possibly because of variations in thickness of the riprap, the slopes and crest are slightly uneven (Photo 1). The horizontal alignment of the crest is good. Riprap is missing from a small area near the spillway (Photo 2). There are no signs of erosion, and no seepage could be detected. The junctions of the embankment with the spillway and the right abutment appear to be tight, with no evidence of separation or movement.

A heavy growth of shrubs and small trees covers the upstream embankment (Photo 3).

#### c. Appurtenant Structures

#### Spillway

The spillway weir appears to be basically sound, but with indications of minor cracking, spalling and erosion (Photo 4). The weir has provisions for attaching flashboards but the boards have been removed (Photo 5). There has been minor erosion and slight undercutting of the channel at the base of the weir. The top of the right wingwall has broken off at the upstream end (Photo 6). The concrete at the downstream end of the left wingwall is spalled and there is evidence of leaching (Photo 7). There is some minor seepage through the abutment rock adjacent to this area.

### Spillway Channel

The spillway channel is cut into natural bedrock and is unlined except for a concrete training wall between the channel and the embankment of the dam (Photo 8). The basalt bedrock is strongly jointed and the finished

surfaces are uneven. The concrete training wall has several vertical cracks extending from the base to the top (Photo 9). Some of the cracks show evidence of leaching. The base of the training wall is eroded at a number of places. At the bottom of the spillway channel the training wall is attached to a toe wall which separates the embankment from the stilling basin.

#### Outlet Works

The only working reservoir outlet is the 24-inch diameter blowoff. It is operated from a control tower in the reservoir with access from a bridge on the right bank (Photo 10). Windows in the control tower or gatehouse are broken out and concrete has spalled from posts supporting the bridge railing.

The water supply outlet has been abandoned and is capped with a steel plate (Photo 11). The 24-inch emergency outlet empties into a stilling basin at the base of the dam. There was some minor leakage from the outlet pipe, indicating that the 2 gate valves were not seated properly.

#### d. Reservoir Area

The reservoir is surrounded by tree-covered, moderate slopes. There is a bridge opening at the upper end of the reservoir, and the reservoir in this area is shallow and partly covered by aquatic vegetation. There is considerable debris in the reservoir near the dam and at the spillway (Photos 3 and 5).

#### e. Downstream Channel

There is a stilling basin at the base of the dam.

The downstream channel has steep tree-covered slopes.

There is a bridge over the channel about 500 feet down-

stream of the dam (Photo 12). Downstream of the bridge the channel follows a steep ravine with a roadway on the right bank above the stream channel. There is a small concrete arch dam on the stream about 1500 feet downstream of the dam. The reservoir of the small dam was dry at the time of the inspection.

#### SECTION 4: OPERATIONAL PROCEDURES

#### 4.1 Procedures

The water supply line downstream of the dam was removed following damage during the 1971 flood. Since the reservoir is no longer used for water supply, there is little regulation. The owner's representatives reported that they sometimes operate the emergency outlet to lower the reservoir in anticipation of high runoff.

#### 4.2 Maintenance of Dam

There has apparently been little maintenance work done on the dam, other than the major repair of the downstream embankment following the overtopping in 1971. Normal maintenance work is done by the owner. No records of maintenance work were found. Several inspection reports are available.

## 4.3 Maintenance of Operating Facilities

It was reported that the emergency outlet is occasionally operated. The former water supply line has been sealed with a steel cap where it exits from the downstream toe of the dam.

## 4.4 Description of Warning System

There is no warning system and no coordination with local authorities. The dam is checked periodically by the owner's personnel.

## 4.5 Evaluation of Operational Adequacy

Maintenance of the dam appears to be generally adequate, although certain repairs are needed.

The present operation of the reservoir should be reviewed, since it is no longer used for water supply. Alternative operation as a flood control facility or for downstream water quality control should be considered.

#### SECTION 5: HYDRAULIC/HYDROLOGIC

#### 5.1 Evaluation of Features

#### a. Design Data

The capacity of West Branch Reservoir is 465 acre feet at the spillway crest and 805 acre feet at the dam crest. The embankment height is 39 feet. In accordance with Corps guidelines, the dam is classified as small in size. Failure or misoperation of the dam would result in overbank flow that would pose a hazard to more than a few lives and could cause excessive property damage downstream. Thus, the dam is classified as high hazard and the Spillway Design Flood (SDF) is the Probable Maximum Flood (PMF).

Data obtained from State files indicate the drainage basin area of the dam is 6.3 square miles. Elevations range from a maximum of 600 feet above mean sea level along the perimeter of the drainage basin to about 180 feet in the valley floor. About 23 percent of the land within the watershed is occupied by commercial, industrial and residential developments. About 1.0 percent of the watershed area is the reservoir of the dam. The drainage basin is delineated on a U.S.G.S. topographic map and is presented on Plate D-1, Appendix D.

The hydraulic and hydrologic features of the dam were evaluated using criteria set forth in the Corps of Engineers, "Recommended Guidelines for Safety Inspection of Dams", and additional guidance and criteria provided by the Philadelphia District, Corps of Engineers. The Probable Maximum Precipitation (PMP) was calculated using Hydrometeorological Report No. 33 and the Hop

Brook reduction factor of 0.80 for misalignment of the storm.

The PMF was calculated using the Corps' computer program HEC-1, Dam Break Version. In computing the PMF the Corps requested that the SCS triangular unit hydrograph with curvilinear transformation be used. The computer program was used to calculate this unit hydrograph from the basin lag. A lag time of 0.9 hours was calculated for the basin and used in the program.

An initial infiltration loss of 0.5 inch and a final infiltration loss rate of 0.05 inch per hour were used in the HEC-1 program to give the rainfall excess. These values were selected because a relatively large percentage of the basin area is developed and the basin slopes are fairly steep. Using the excess rainfall and the unit hydrograph, the program computed the peak inflows of the 25 percent, 50 percent, 75 percent and 100 percent PMF. These inflows are approximately 6,630 cfs, 13,260 cfs, 19,880 cfs, and 26,510 cfs, respectively.

The various percentages of the PMF inflow hydrograph were routed through the reservoir using the Modified Puls Method by the HEC-1DB program. The peak outflow of the 25 percent, 50 percent, 75 percent and 100 percent PMF were calculated to be approximately 5580 cfs, 12,580 cfs, 19,180 cfs and 25,760 cfs, respectively. The flood routings indicate that all floods greater than about 25 percent of the PMF will overtop the dam. A plot of percent PMF versus peak outflow discharge is presented as Plate D-2 in Appendix D.

The spillway and overtop stage-discharge rating curve used in the flood routings was calculated using the weir equation and assuming free overflow across the entire

length of the dam and spillway. The spillway is a modified ogee crest weir with a reported discharge coefficient of 3.6. The main embankment is a round-crested weir with an estimated discharge coefficient of 3.1. The reservoir stage-storage curve was determined from U.S.G.S. 7.5 - minute topographic maps and data obtained from State files. This stage-storage curve was extended above the dam crest to include surcharge storage during peak flood discharges. In the reservoir routing computations possible discharges through the outlet works were excluded because their capacity is small compared to the PMF and because of the possibility that the outlet valves may be closed. The stage-storage and the spillway and overtop stage-discharge curves are presented in Appendix D as Plates D-3 and D-4, respectively.

The various percentages of the PMF were routed 0.7 miles downstream to a point where the stream channel crosses under Chimney Rock Road. At this location is a filtration plant and associated structures, and just downstream of the plant is the very small community of Chimney Rock. These routings were made to determine downstream flooding characteristics without dam failure. The flooding characteristics, assuming no breach of the dam, were compared to those that would result assuming the dam fails because of the inadequate capacity of its spillway. From this comparison the seriousness of the spillway's inadequacy was assessed.

The hydraulic parameters used in the HEC-1 program for the downstream routing calculations were estimated based on observations made in the field and information obtained from U.S.G.S. topographic maps. The locations of the cross-sections used in the routing calculations are shown on page D-6, Appendix D.

The breach parameters used in the HEC-1 analysis are: the breach is trapezoidal in shape with 45-degree side slopes, is 190 feet wide at the base, will extend to the approximate original reservoir floor elevation (160'), will begin breaching when the dam is first overtopped, and will develop to its maximum size in 6.0 hours.

The flooding characteristic at the filtration plant and the nearby rock quarry are summarized for the various floods in the following tabulation. At this location there would be a high hazard to personnel and property.

	25% PMF	50% PMF	75% PMF	100% PMF
No Breaching				
Peak Discharge, cfs	5540	12,500	18,960	25,530
Peak Flow Depth, ft	7.9	11.1	13.0	14.6
Peak Flow Width, ft	190	275	320	355
Peak Flow Velocity,				
fps	8.2	8.8	9.5	10.1
Breaching				
Peak Discharge, cfs	6320	14,670	21,830	28,360
Peak Flow Depth, ft	8.4	11.8	13.8	15.2
Peak Flow Width, ft	200	295	340	370
Peak Flow Velocity,				
fps	8.2	9.1	9.7	10.3

Information obtained from the State's files indicate that the drain for the reservoir is a 24-inch diameter pipe. Using the orifice flow equation and assuming no tailwater at the outlet or inflows into the reservoir, the time required to drain the reservoir from the spillway crest full condition was calculated to be about 3.5 days.

### b. Experience Data

Records of lake levels are not maintained for this site. The reservoir is unregulated and unused. The reservoir is generally at or near its maximum storage level. It is known that the dam was overtopped in 1971.

### c. Visual Observations

There is a well defined channel downstream of the embankment. No dwellings were observed on the banks of the immediate downstream channel. About 500 feet downstream of the dam is a bridge that, during high flows, would constrict flows if the dam does not fail. The constriction would tend to attenuate the downstream flood.

### d. Overtopping Potential

As indicated in Section 5.1-a, West Branch Reservoir
Dam spillway can pass only 25 percent of the PMF.
During the PMF the embankment would be overtopped for about
5.7 hours and would have a maximum overtopping stage about
6.2 feet above the dam crest. These overtopping heights
assume the dam remains in its current condition. This
amount of overtopping would probably result in a dam breach.

The data tabulated in Section 5.1-a were used to assess the degree of significance that overtopping failure would increase the downstream hazard. As shown in the tabulation, for all the floods that were studied the flooding characteristics assuming the dam fails are not significantly different from those that would exist if the dam does not fail. Thus, failure caused by inadequate spillway capacity does not significantly increase the downstream hazard and the spillway should be classified as Inadequate.

### SECTION 6: STRUCTURAL STABILITY

### 6.1 Evaluation of Structural Stability

### a. Visual Observations

The visual inspection did not indicate any signs of structural instability of the embankment. The crest alignment is good, the downstream slope is reasonably even, and no indications of seepage through the embankment were observed.

The concrete spillway appears to be in fairly good condition, although there is some erosion at the base of the weir and the right wingwall has been damaged. The natural rock spillway channel may be subject to some erosion and frost action along the joints, but basically the rock appears to be competent. The concrete training wall on the right side of the spillway channel is cracked in several places and the concrete is badly eroded from the base of the wall at several locations.

### b. Design and Construction Data

The design of the dam was changed during construction, so that most of the available design drawings do not show the present configuration of the dam. The designs of the embankment slopes and core wall appear to be adequate, and construction reports indicate that the core wall was founded well into bedrock. Very little is known about the placement of embankment materials and nothing is known of the as-built properties of the materials.

### c. Operating Records

There are no records of reservoir operation. There is

no instrumentation to detect seepage or measure pore pressures or phreatic levels in the embankment. No recent survey of the dam is known to exist.

### d. Post-Construction Changes

No records are available of the work done to repair the embankment following the 1971 overtopping, and the condition of the core wall following the flood is not known. Visually, the workmanship seems to have been of good quality.

### e. Seismic Stability

The dam is located in Seismic Zone 1 in which it may be generally assumed that there is no hazard from earthquake, provided static stability conditions are satisfactory and conventional safety margins exist. Although the dam appears to have adquate static stability, a stability analysis would be needed to verify this.

### SECTION 7: ASSESSMENT, RECOMMENDATIONS AND PROPOSED REMEDIAL MEASURES

### 7.1 Dam Assessment

### a. Safety

The spillway of the dam is inadequate and can pass only 25 percent of the Probable Maximum Flood. The dam was overtopped in 1971, causing considerable damage to the downstream embankment.

Structurally, the dam appears to be adequate. The slopes and crest are without any major discontinuities or evidence of distress. Although nothing is known of the embankment materials, it is known that the dam has a concrete core wall that extends into bedrock. However, the core wall should not be expected to provide structural stability if overtopping should again result in removal of embankment materials.

The spillway channel training wall is cracked, eroded and in need of repair.

### b. Adequacy of Information

Data are insufficient to evaluate the stability of the dam, since little is known of the design or construction of the dam, and nothing is known of the as-built properties of the embankment materials. The present condition of the core wall is not known. Insofar as is known, the dam has not been surveyed in recent years.

### c. Urgency

The operation of the reservoir should be reviewed as soon as possible, as should implementation of a down-

stream warning system. Other measures as itemized below are of a less urgent nature and should be implemented in the near future.

### d. Necessity for Additional Data/Evaluation

Corps of Engineers Guidelines require that, in general, seepage and stability analyses should be on record for all dams in the high hazard category. In view of the fact that West Branch Reservoir Dam is a high hazard dam which has an inadquate spillway and which has been overtopped, it is recommended that a program of soil borings and laboratory tests be performed by the owners to determine the physical properties of the dam and foundation materials so that seepage and stability analyses can be performed. Such a program should also include the installation of piezometers on the crest and downstream slope to establish the internal water levels of the dam. Evaluation of all data should be made by experienced geotechnical and soils engineers.

It is also recommended that the dam be surveyed to verify the existing crest elevation and side slopes. This could become the basis for periodic monitoring surveys in the future.

More detailed and sophisticated hydraulic and hydrologic studies to more accurately determine the spillway capacity should be undertaken by the owner within six months. Remedial action, as a result of these studies, should be initiated within one year.

### 7.2 Remedial Measures

### a. Alternatives

It is recommended that as soon as possible the owner investigate alternative methods of operation of the reservoir, since it is no longer used for water supply. Such alternatives could influence the means of obtaining adequate spillway capacity and eliminating future overtopping of the dam. The alternatives might include its conversion to a flood control facility by construction of a new low-level spillway to supplement the existing spillway. Another alternative is to maintain a lower operating level by installing a low-level standpipe downstream of the emergency outlet valve. Other alternatives might suggest themselves, including, of course, abandonment and breaching of the dam.

### Operation and Maintenance Procedures

The following operation and maintenance procedures are recommended:

- 1. Repair the cracked and eroded areas of the spillway channel training wall.
- Check the emergency outlet valves to see that they are functioning properly. Regularly operate the outlet in the future to check its performance.
- Install and periodically monitor the piezometers and survey markers as recommended above in Section 7.1-d.
- 4. Remove all shrubs and trees from the embankment and clean floating debris from the spillway area.

- 5. Inspect the dam annually, using the criteria set forth in the Corps of Engineers Guidelines.
- 7. Keep records of all maintenance work.
- 8. Establish and implement an emergency warning plan to provide adequate warning to downstream residents. Also, surveillance of the dam should be provided during periods of heavy precipitation.

### EMBANKMENT

VISUAL EXAMINATION OF	OBSERVATIONS	REMARKS OR RECONSENDATIONS
SURFACE CRACKS	Not observable because of thick rock riprap cover.	
UNUSUAL MOVENENT OR CRACKING AT OR BEYOND THE TOE	No movement or cracking could be detected. An extension of the spillway channel training wall protects the toe of the embankment from the stilling basin.	
SLOUGHING OR EROSION OF ENEANCHMENT AND ABUTHENT SLOPES	None visible. Slightly undulating surface.	
VERTICAL AND HORIZONTAL ALINENENT OF THE CREST	Vertical alignment slightly uneven, probably due to variations in thick rip- rap cover. Horizontal alignment good.	
RIPRAP PAILURES	Small area of riprap missing from crest near spillway. Riprap is quarried basalt.	Missing riprap should be replaced.

### EMBANGENT

VISUAL EXAMINATION OF	OBSERVATIONS	REMARKS OR RECONMENDATIONS
VEGETATION	Heavy growth of shrubs on upstream side, also considerable debris.	Shrubs should be removed.
JUNCTION OF EMBANGENT AND ABUTHENT, SPILLMAY AND DAM	Abutments are bedrock. Junctions appear to be tight.	
ANY NOTICEABLE SEEPAGE	None observed through embankment. Some minor seepage through bedrock at left abutment in spillway channel.	
STAFF CAGE AND RECORDER	Staff gage painted on intake tower, water level of reservoir indicated to be 197.3 feet.	Gage elevations apparently are a local datum, since reservoir was about 1.7 ft. below spillway crest which is Elev. 187 ft.
DRAINS	None observed.

## APPENDIX C

REGIONAL GEOLOGY - PIEDMONT LOWLANDS

#### REGIONAL GEOLOGY - PIEDMONT LOWLANDS

#### Physiography

The Piedmont Lowlands Province of New Jersey lies northwest of a line approximately between Trenton and Perth Amboy and southeast of an approximate line between Milford on the Delaware River and Mahwah near the New York State border. Physiographically, the province is situated between the predominantly Precambrian age New Jersey Highlands Province to the northwest and the typically unconsolidated Creataceous age and younger sediments of the Coastal Plain Province to the southeast. (See Figure C-1).

#### Bedrock

The Piedmont Lowlands, encompassing about onefifth of the state, is characterized by northwestward
dipping bedrock composed of interbedded red shales,
siltstones and sandstones of Triassic and Jurassic age
and igneous basalt extrusions (lava flows) and diabase
intrusions of Jurassic age. The sedimentary rocks have
been eroded to a broad southeastward sloping piedmont
plain. The northwest border of the province is a northeast-southwest trending fault zone (Ramapo Fault)
which truncates the sedimentary beds. Total vertical
displacement on the fault may reach 10,000 feet.

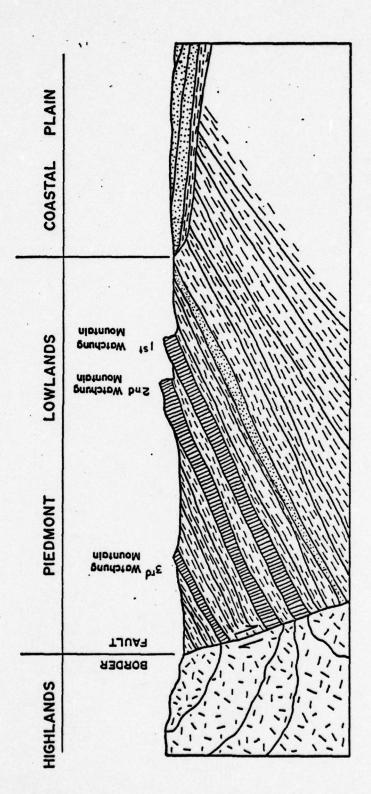

The gently rolling lowland topography of the piedmont lowlands is pierced by long asymetric ridges of hard

and resistant igneous rocks which were intruded into or on top of the sedimentary sequences. With the subsequent erosion of the softer sedimentary rocks, these igneous formations have been left standing, often in bold relief, up to 400 ft. above the surrounding plains. The igneous bodies composed of diabase and basalt form the Palisades along the Hudson River and the three Watchung Mountain ridges of the central Piedmont. The ridges are all steeper on the southeast with gentle dip slopes to the northwest.

#### Overburden

The Pleistocene Age Wisconsin continental glacier has smoothed and filled approximately the northern half of the province. The terminal moraine of the glacier extends from Perth Amboy to Summit then northwestward to Morris Plains. North of the morainal line the soils characteristically consist of glacial tills overlying the bedrock with scattered overlying stratified outwash deposits. At least three large glacial lakes occupied portions of the area north of the moraine at different periods, resulting in a relatively flat topography composed predominantly of silts and clays.

South of the terminal moraine, most of the overburden consists of alluvial deposits overlying a more highly developed weathered transition zone on top of the bedrock. Some highly weathered tills of pre-Wisconsin glaciation can be found on the top of intervalley ridges. Much of the alluvium is glacial outwash.

West branch reservoir dan

BOUND BROOK WATER COMPANY

APPLICATION No. 118

LOCATION 25.33.4.4.1.

On September 20, 1929 a letter was received from Mr. Clyde Potts, Consulting Engineer, stating that since a fault and a seam has been discovered in the foundation for the proposed west spillway of the above dampit is desired to omit the west spillway and to construct a single larger spillway at the site of the proposed east spillway. The letter was accompanied by a copy of the attached drawing.

Examination of the drawing shows that the single spillway as designed will discharge 2,435 second feet or 386 cubic feet per second per square mile of drainage area with the flash boards on, as compared with 373 by the two spillways formerly proposed.

The spillway channel will discharge 2,435 second feet with a depth of flow of 4.1 feet and a velocity of 22 feet per second. Training walls are provided adequate to protect the east bank and the downstream fill from erosian.

On September 21. 1929 the site for the single spillway was inspected by the writer in company with Kr. Badeau of Kr. Potts's office, Kr. Edgar, the Contractor, and Kr. M. E. Johnson, Assistant State Geologist.

Rook has been uncovered in the spillway channel and at the downstream side of the spillway structure. The rook is sound and satisfactory.

At the west end of the dam trench for core wall has been carried.

back into the bank 10 feet beyond the flow line and into solid ledge rock
to depths of from 4 to 12 feet. The fault crossing this trench has been
eleansed out to its full width of 2 feet and to a depth of 12 feet for a disp
tance of 15 feet above the core wall and will be filled with concrete. The
horisontal joint which appears in the rock below the core wall was examined by
Mr. Johnson and pronounced to be an insignificant cooling crack in the gneiss.

Core wall is 100% complete. Upstrenm fill 80% and downstream fill 90% complete. Compacting is satisfactory. Spillway channel excavation 40% complete.

The writer recommends the acceptance of the attached drawing as a change in detail under the plans approved November 9th, 1927, and the approval of the foundation for the single spillway at the east end of the dam.

If these recommendations are accepted by the Chief Engineer, Mr. Potts's office should be notified.

Trenton, N. J., September 24, 1929. John N. Brooks, Hydraulic Engineer.

Memorandum re.

Dam Application No. 118, West Branch Reservoir, Bound Brook Water Co.

On March 21, 1950 Mr. Weston Gavett of Mr. Clyde Potts' office called at the Trenton office and on behalf of Mr. E. D. LaTourette, President of the Bound Brook Water Company, requested permission to raise the crest of the concrete spillway and the crest of the flashboards one foot above the elevation shown on the drawing approved by our Chief Engineer on September 25, 1929. The purpose of the increase in height is to obtain additional storage. The concrete weir forming the spillway crest has not yet been poured and Mr. Gavett asked for a prompt ruling on the request so that it can be poured soon.

Inspection of the dam on March 14, 1930 showed all of the work practically completed except the spillway weir and the gate house superstructure. The pond was half filled.

The spillway details approved by the Chief Engineer on September 25, 1929 show an 0.3. section concrete weir with a crest length of 66.0 feet at Elevation 187.0 surmounted by wood flashboards designed to go out in high water, having their crest at Elevation 188.0: the top of the earth dam at Elevation 194.5 and the top of the concrete core wall at Elevation 193.0. With water at top of core wall this gives 5.0 ft. head over the flashboards with 1.5 ft. freeboard and a discharge of 2435 sec. ft. or 386 sec. ft. per sq. mile from 6.3 sq. miles of watershed.

With the flashboards washed out the capacity would be about 500 sec. ft. per sq. mi.

With the crests raised as requested the discharge capacity with flashboards in place would be but 1700 sec. ft. or 276 sec. ft. per sq. mile, and with flashboards washed out about 386 sec. ft. per sq. mi.

Our flood flow studies indicate a maximum flood of 470 sec. ft. per square mile and I recommend that the request be denied.

Trenton, N. J. March 21, 1930. John N. Brooks, Assistant Division Engineer.
